

Build Optimization In Angular

Your Angular application is
larger than necessary. 🙄

1. Your Angular bundle is BIG?

Standalone APIs might be the reason it shouldn't be.

Alternatives:

- Why Is Your Angular Bundle So Heavy?
- Stop Shipping Unused Angular Code 
- "This One Angular Change Shrinks Your Build"

🔥 2. Lazy Loading Beyond Routes (Component-Level Lazy Loading)

Using dynamic import() for:

- Heavy components
- Charts, editors, dashboards
- Feature-specific utilities

👉 Talking point: “Route-based lazy loading is not enough anymore.”

🔥 4. ESBuild vs Webpack: Why Angular Builds Are Faster Than Ever ESBuild Changed Angular Forever

How Angular's switch to ESBuild improves:

- Build time
- Rebuild speed
- CI/CD efficiency

👉 Talking point: “Build optimization is not just about size, it's about developer velocity.”

🔥 5. Optimizing Third-Party Libraries in Angular Builds

Common mistakes that bloat bundles:

- Importing entire libraries instead of functions
- Using non-tree-shakable packages
- Ignoring ESM builds

👉 Talking point: “One bad library can add 300KB to your bundle.”
